

Seeing Titan with VIMS infrared eyes during 13 years : from changing atmospheric features over the poles to global surface mapping

S. Le Mouélic, S. Rodriguez, C. Sotin, T. Cornet, B. Rousseau, R. Robidel, J. W. Barnes, R. H. Brown, B. J. Buratti, K. H. Baines, R. N. Clark, P. D. Nicholson, B. Seignvert, P. Rannou

The Visual and Infrared Mapping Spectrometer (VIMS)

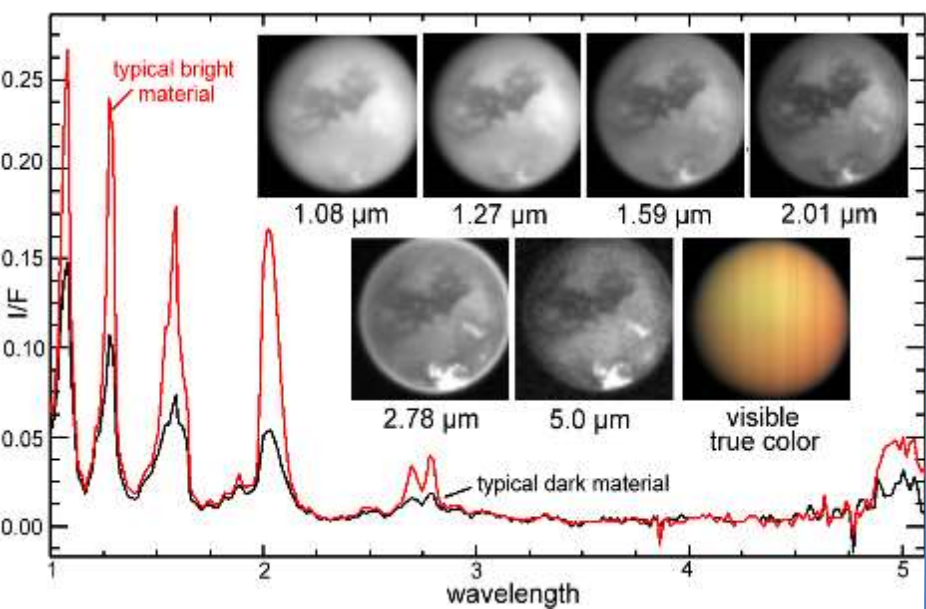

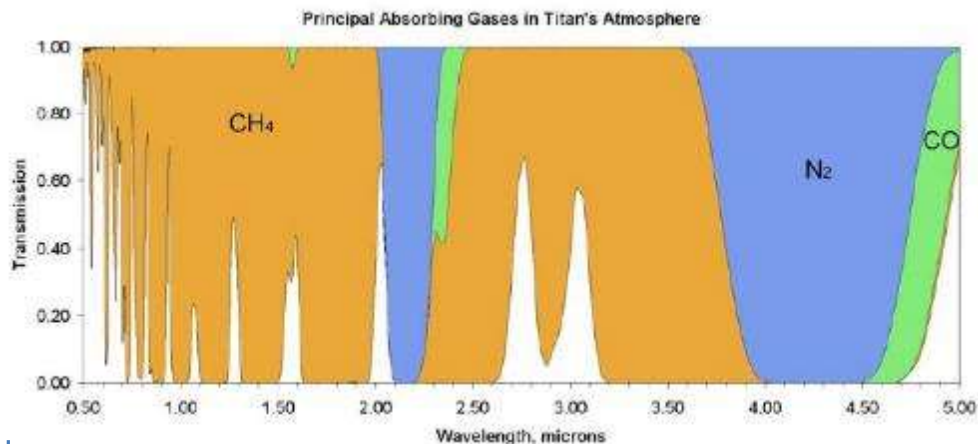

→ Imaging spectrometer with up to 64x64 pixels, in 352 spectral channels from 0.3 to 5.1 μm

→ The surface is seen in 7 “windows”

→ The spectral dimension can be used to detect and map the clouds

→ ~60000 individual data “cubes”

(x, y, λ) : two spatial dimensions and one spectral dimension

1 - Atmospheric features over the poles

First evidence of a northern polar cloud

- Griffith et al. (2005) → detection of a vast polar ethane cloud at all longitudes, and latitudes from 56° up to 68°

Albedo at $2.8 \mu\text{m}$ (Griffith et al., Science 2005)

- Best imaging conditions in Dec. 2006

Le Mouélic et al., Planet Space Sci. 60, 2012

Global distribution and temporal evolution of clouds

- Global study of the VIMS data set (Rodriguez et al., 2009, 2011, ...), mostly focused on tropospheric clouds
- Distribution in agreement with complementary ISS studies (Turtle et al., 2011, 2018)

North pole

Fractional 2004-2010 VIMS cloud detection maps

South pole

Rodriguez et al., Nature, 2009

Our approach : Systematic cartographic survey of the poles

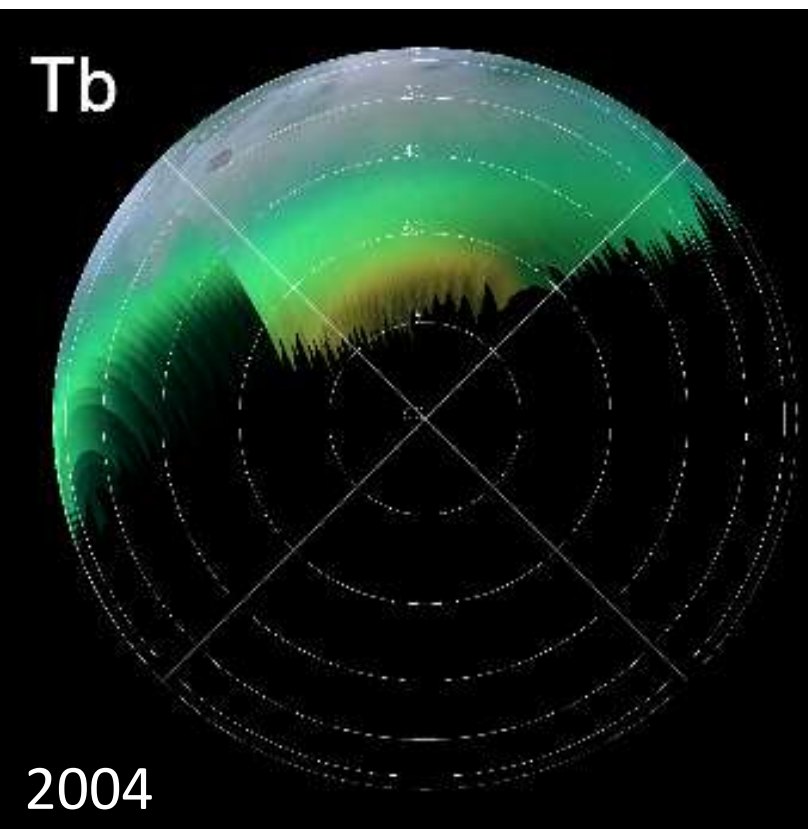

- Computation of global hyperspectral mosaics for 127 targeted flybys between 2004 and 2017
- Computation of global maps at diagnostic wavelengths

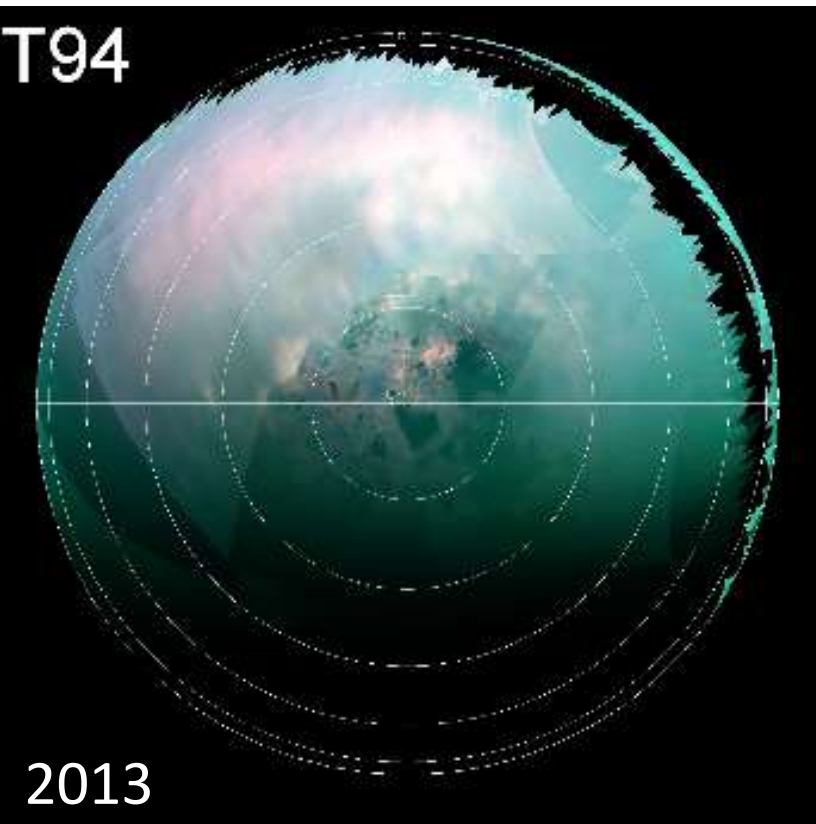

The north pole

- The north cloud system was already present in first flybys

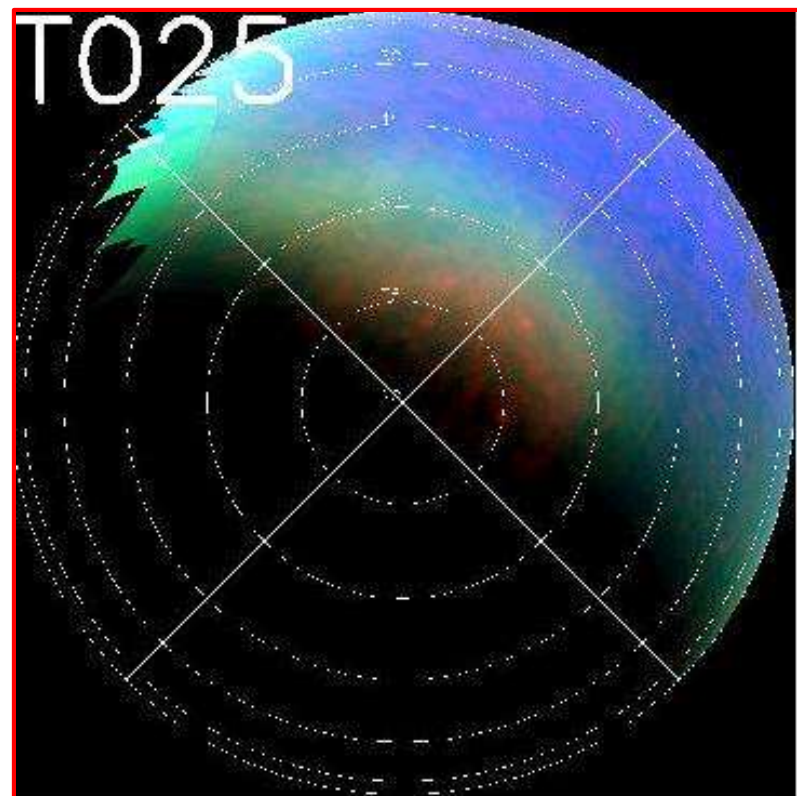

The north pole

- It vanished at the equinox, revealing progressively the underlying lakes

HCN spectral signatures in the north

- Can be tracked down up to 2008 in our set of global maps,

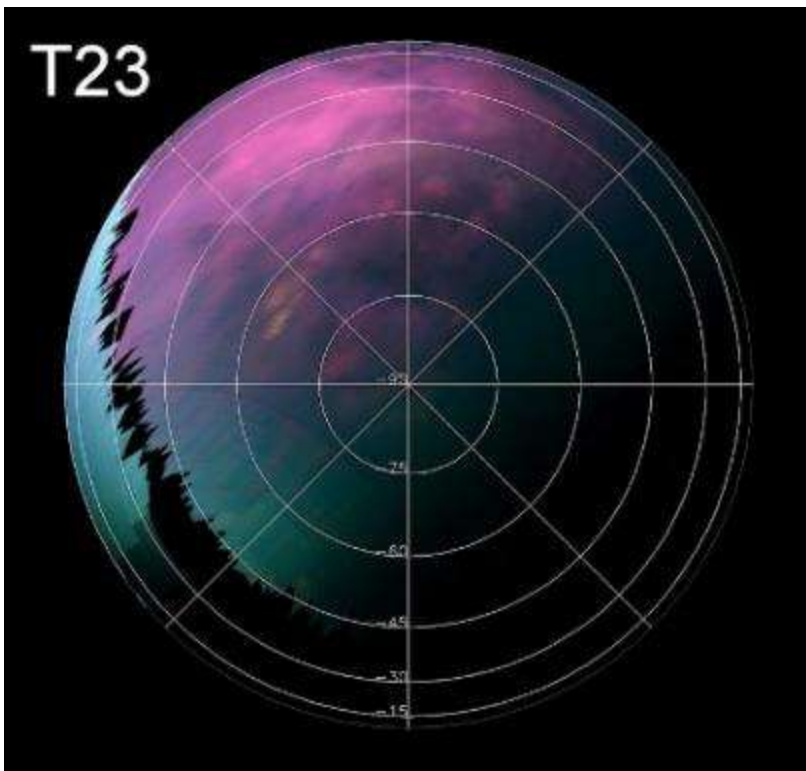

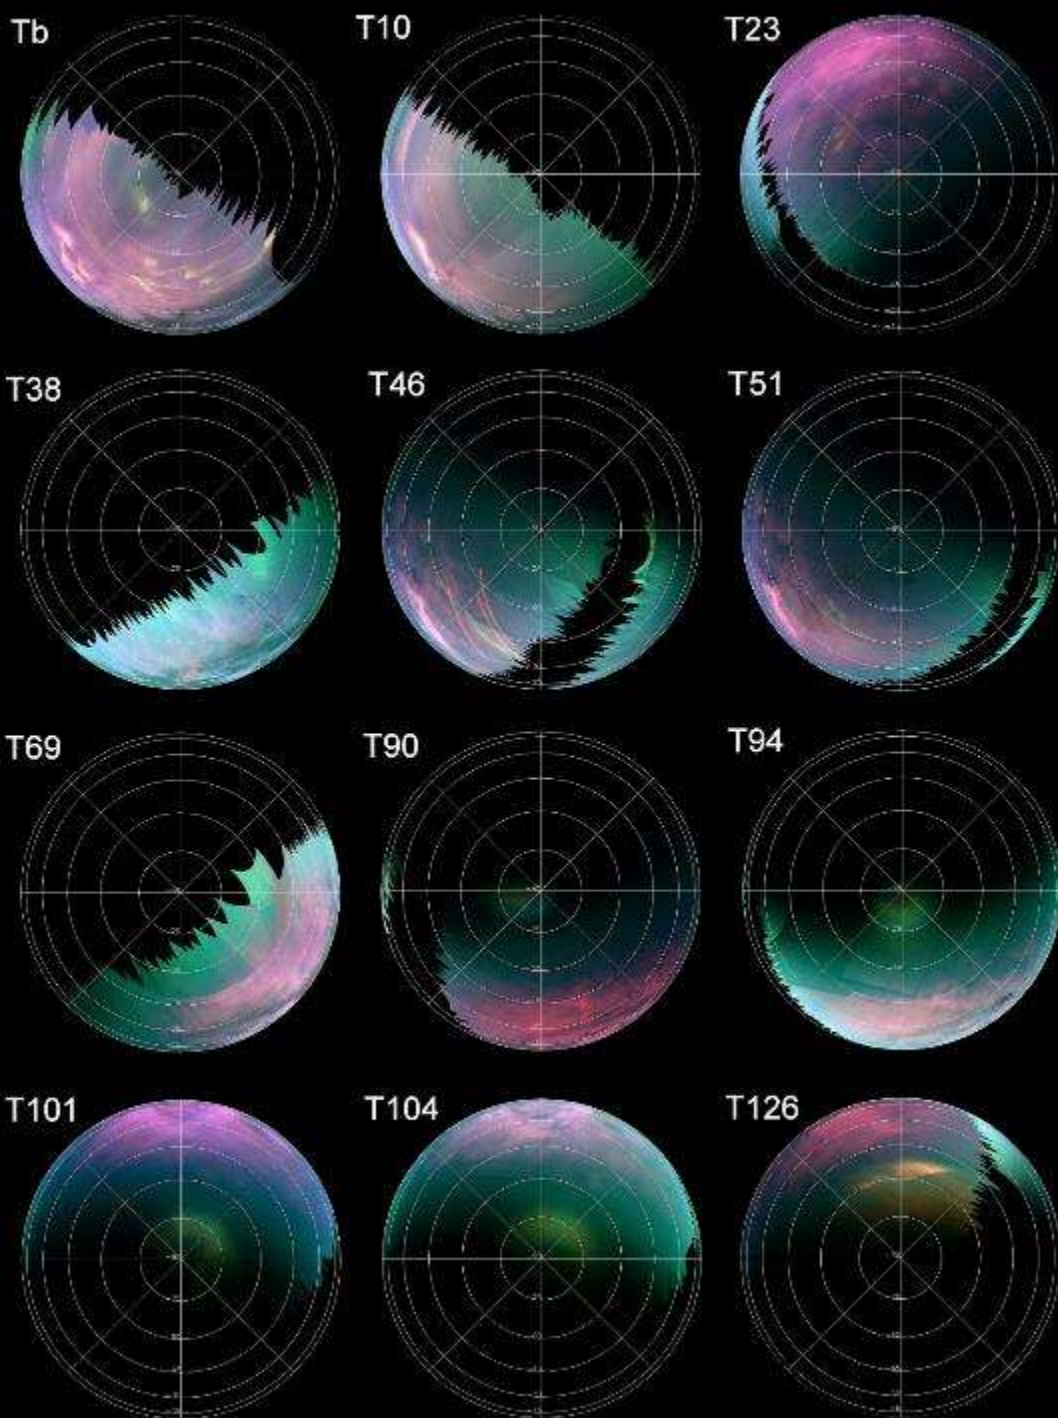

R=4.78 μm
G=2.78 μm
B=2.01 μm

T50

The south pole

- Clear skies at the beginning of the mission

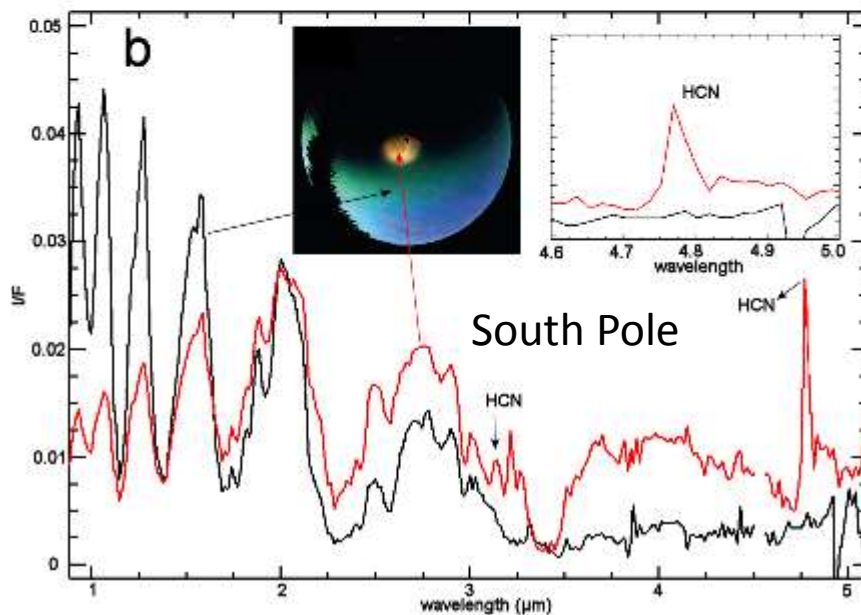

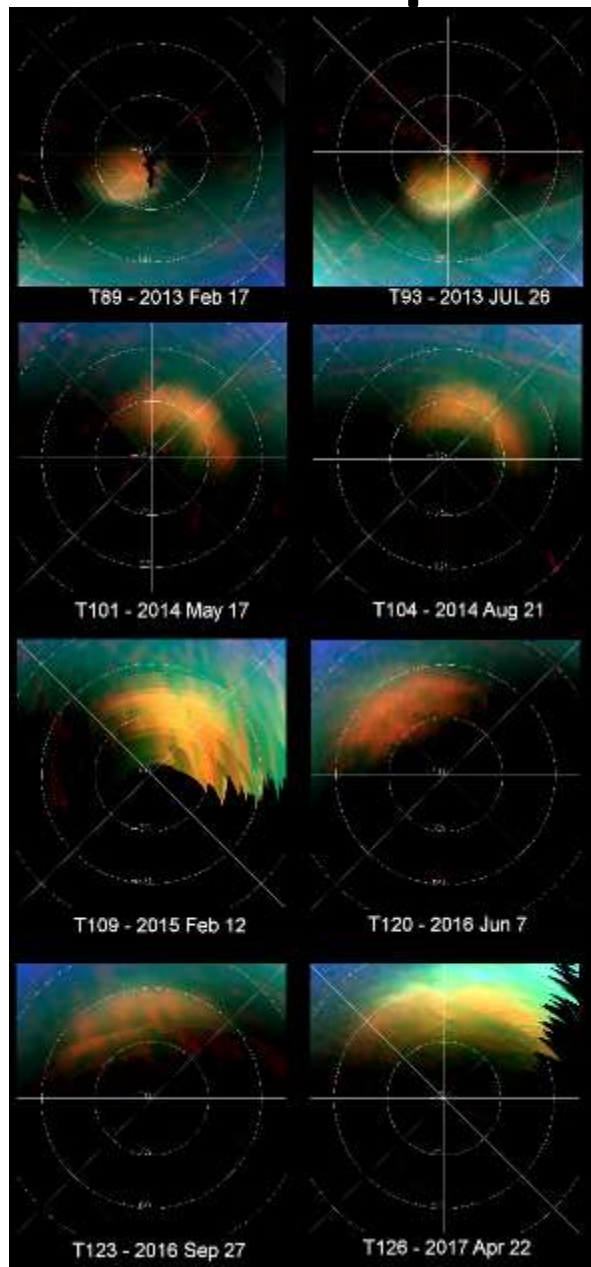

The south pole

- Clear skies at the beginning of the mission
- An HCN-rich cloud appeared in 2012

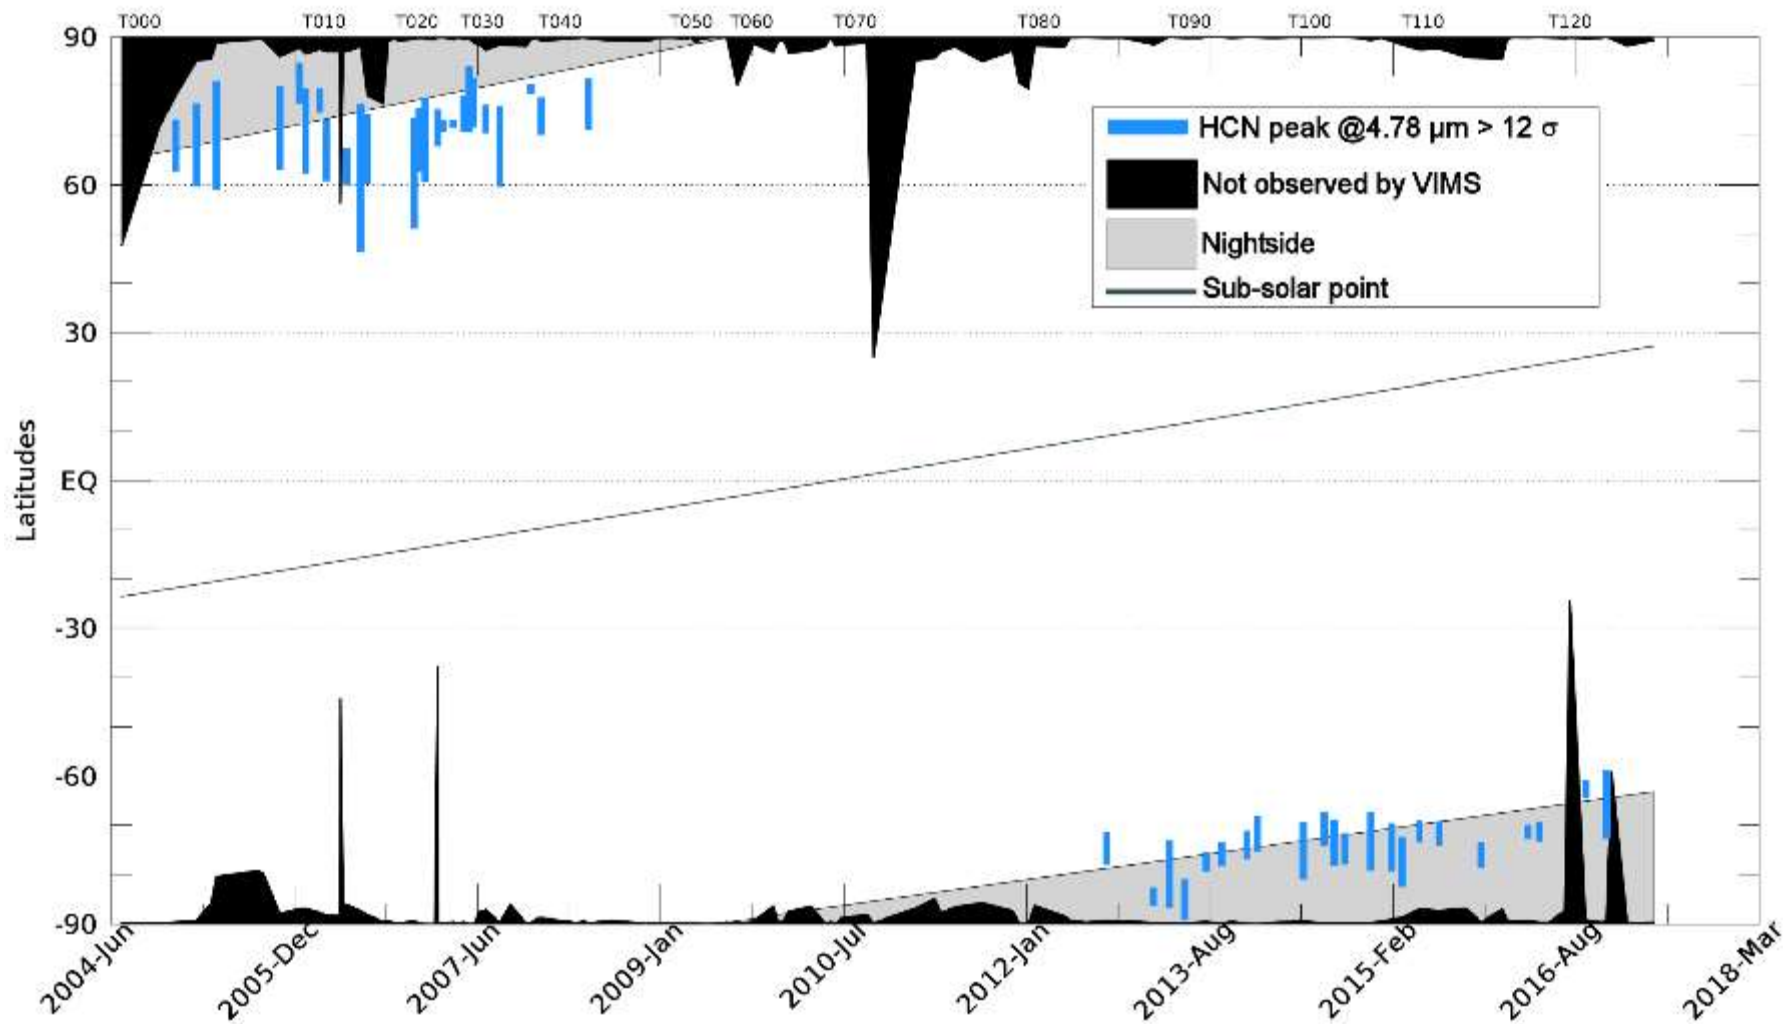

The south pole

Temporal evolution

- Evolution of the HCN signature with time

Summary of the poles survey

- Monitoring the seasonal evolution over half a Titan year...

2-Seeing the surface through the atmosphere : a cartographic challenge (nightmare 😊?)

Building a global hyperspectral mosaic

- **Radiometric calibration** of the cubes (dark subtraction, flat field,...) and computation of navigation files (SPICE)
- **Sort of the cubes** with low spatial resolutions used as background and high resolutions put on top
- **Set of filters** to remove cubes acquired in extreme geometry
 - $i < 80^\circ$
 - $e < 80^\circ$
 - $\text{phase} < 110^\circ$
 - $\text{airmass} (1/\cos i + 1/\cos e) < 7$
 - time exposure (avoid saturated pixels) : between 20 and 300 ms
- **mosaic at 32 pixels/degree** (1.4 km/pixel) of the 256 spectral channels between 1 and 5 μm
- **Define series of processing steps to remove seams and emphasize spectral (compositional) variations**

Global mosaic and corresponding geometry

→ the **seams** are due to the varying observing geometry

- Absorption, scattering by gas/aerosols (**i,e,phi,lambda,airmass**)
- Aerosol and surface **photometric function**
- Residual calibration artifacts (**wavelength shift**)
- **Temporal changes** (clouds/surface/atmosphere) ...

Mosaic at 5 μm : the easiest case

- Almost no aerosol scattering \rightarrow only needs to be corrected from surface photometry

Mosaic at 5 μm : the easiest case

- Divided by a Lunar lambert and rayleigh phase function (Cornet et al., 2012)

$$A \mu_0 / (\mu_0 + \mu) P(g) + (1 - A) \mu_0 \text{ with } A=0.285$$

More complicated case: the 2.03 μm window

- Uncorrected map

2.03 μm window divided by photometric function

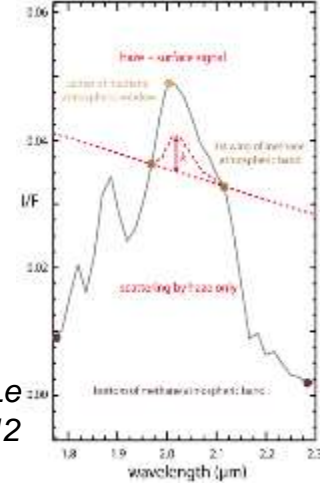

- Map corrected from surface photometry only (☹)

2.03 μm window minus band wings divided by photometric function

- Map corrected from atmosphere & surface photometry

Approach from Le
Mouélic et al., PSS, 2012

Comparison with ISS (2015 public basemap)

Combining wavelengths to produce RGB false color composites

- Map corrected from surface photometry & atmosphere
- R= 2 μm , G= 1.59 μm , B=1.27 μm corrected from scattering & geometry

The most powerful tool in surface mapping: using band ratios...

Can we do this for Titan ?

R=1000 nm, G=900 nm, B=415 nm

R= 750/415 nm, G=750/950 nm, B=415/750 nm

→ The **band ratios** remove albedo variations and the local slopes effects and **better emphasize subtle spectral variations** than RGB composites of single bands.

♦ **Drawback** : Extremely sensitive to calibration residuals (& atmospheric effects on Titan)

First try of band ratios on the global data set

- $R=1.59/1.27$, $G=2.03/1.27$, $B=1.27/1.08 \mu\text{m}$: ☹️

→ Is this modern art ? Not usable for science...

After a lot of head scratch...

- $R=1.59/1.27$, $G=2.03/1.27$, $B=1.27/1.08 \mu\text{m}$
- Refinement of the wavelength selection and calibration - ☺
brown colors=dune fields

After a lot of head scratch...

- $R=1.59/1.27$, $G=2.03/1.27$, $B=1.27/1.08 \mu\text{m}$
- Refinement of the wavelength selection and calibration
- Additional atmospheric empirical cleaning filter
(dependence with airmass) - ☺

Zoom on the Huygens site...

DISR

- Some places are well imaged
- Some others will require a new spacecraft...

VIMS

Orthographic views

Thanks for your attention...

...waiting for new Titan images

Cassini VIMS Data Portal

by the *Laboratoire de Planétologie et Géodynamique (LPG)* of Nantes

This website provides an overview of the Cassini VIMS dataset acquired between October 2004 and September 2017. For now, only the public targeted icy moons flybys are available. You can already dive into these data by clicking on the flybys you are interested on:

Titan Enceladus Dione Rhea Phoebe Hyperion Iapetus
